# Sedimentary Basins Provide Clues About Earth's Past Climate

Posted in | [Climate Change \(/news-category.aspx?CatID=6\)](/news-category.aspx?CatID=6)[Download PDF Copy](#)[Request Quote](#)Written by [AZoCleantech](#)[f \(https://www.facebook.com/AZONetwork/\)](https://www.facebook.com/AZONetwork/)

**Forces that shape the Earth's surface are recorded in a number of natural records, from tree rings to cave formations.**

[t \(https://twitter.com/AZOcleantech\)](https://twitter.com/AZOcleantech)[/AZoCleantech](#)

In a recent study, researchers from The University of Texas at Austin show that another natural record - sediments packed together at basin margins - offers scientists a powerful tool for understanding the forces that shaped our planet over millions of years, with implications on present day understanding

The study was published in the journal *Geology* and uses a computer model to connect distinct patterns in the sedimentary deposits to shifts in climate and tectonic activity.

Geoscientists have long looked to sedimentary basins for clues about Earth's past

Directory (/directory.aspx)

climate. That's because sediment supply is closely linked to environmental factors,  
 such as rainfall or snowfall, that influence sediment creation through erosion and  
 sediment transport across a landscape and into a basin. Tectonic factors also  
 influence sediment creation, with increasing uplift associated with more sediment  
 and decreasing uplift with less.

However, despite knowledge of sediment supply being linked with climate and  
 tectonics, the researchers said little is known about how changes in these  
 phenomena directly influence how sediment is deposited along basin margins over  
 long time scales.

(https://twitter.com

This study changes that, Zoltán said, using the open-source computer program  
 pyBadlands to create a "source-to-sink" 3D model that tracks how changes in  
 precipitation, tectonic uplift and sea level influence sediment erosion and deposition.  
 The model uses topography inspired by the Himalaya Mountains and Indus River  
 Delta to track the sediment as it makes its way from the mountains, through a river  
 system, and settles into a basin margin over millions of years.

*"This is one of the first [models] to put the landscape evolution part with the stratigraphic  
 response, depositional response, and do it in 3D," Covault said. "Lianyu has made a really  
 great step in putting this all together."*

The researchers ran 14 different scenarios

## Related Stories

- each with a different climatic, tectonic, and sea level settings - over a simulated time period of 50 million years to investigate changes in landscape topography and sediment deposition.

The different scenarios created distinct patterns in sediment deposition, which allowed the researchers to draw general conclusions about how tectonic and climatic factors affect basin margin growth. For example, changes in uplift take millions of years to affect change in the basin margin sediments, but once those changes are in effect, they set a new baseline for behavior. In contrast, changes in precipitation cause much more abrupt change, followed by a return to the depositional behavior observed before the climate shift.

<https://twitter.com/AzoCleantech>

The scenarios showed that sea level rise could potentially complicate the delivery of the signal of tectonic change into the basin. For example, an increase in sea level flooded coastal regions and interfered with sediment reaching a basin margin. But when this scenario was paired with increased precipitation, the sediment supply was large enough to make it to the basin margin.

Gary Hampson, a professor at Imperial College London who was not part of the study, said that the model provides important guidelines for geoscientists looking to reconstruct Earth's past.

*"The results increase the confidence with which geoscientists can interpret tectonic and climatic histories in the geologic archives of basin margins," he said.*
